

TRG Networking — merged site hand-off

The Hostinger design language is the base theme. Everything valuable from the Lovable build has been transplanted into it and rebuilt so it behaves natively: same fonts, same blue, same spacing scale, same card treatment.

0. First, how editing works now — please read

Your brief asked for a note showing where to edit the new sections **inside the Hostinger dashboard**. I need to be straight with you about that.

This is not a Hostinger Horizons site any more, and it cannot be. Horizons is an AI website builder: you describe a change in its chat and it regenerates the site. There is no way to take a second site built somewhere else, merge it in, and have the result still be editable that way — Horizons did not author this code, so its editor cannot manage it.

What you have instead is a normal, self-contained website that runs on any standard hosting, including Hostinger's ordinary web hosting. That brings real advantages: it is yours outright, no builder subscription controls it, it loads faster, and it is not locked to one platform ever again.

The trade is that content changes happen in **two plain text files** rather than a chat box. Section 1 below is the map. Anyone comfortable editing a document can make most changes — they are lists of text, not layout code — and I am happy to make them for you either way.

If keeping the Horizons AI editor really matters more than merging the two sites, tell me now, because that is a different project and I would rather say so than let you find out later.

1. Where to edit things

Almost everything you will want to change lives in **two files**. You do not need to touch layout code to change copy, phone numbers, services or industries.

src/data/site.js — everything that repeats across the site

What you want to change	Edit this
Phone number, email, address, LinkedIn	<code>company</code>
The four homepage counters	<code>stats</code>
Header / footer / dropdown menus	<code>mainNav</code> , <code>servicesNav</code> , <code>industriesNav</code>
Homepage service cards	<code>services</code>
Homepage industry list	<code>industries</code>
Client quotes	<code>testimonials</code>
Hero badges ("Microsoft Partner" etc.)	<code>heroBadges</code>
Partner logo strip	<code>partners</code>
The "Service of interest" dropdown on the form	<code>serviceOptions</code>

Change the phone number in `company` and it updates in the top bar, the mobile menu, the footer, every call-to-action band and every service page at once.

src/data/detailPages.js — the twelve service and industry pages

Each page is one object. To edit the CMMC page, find `'cmmc-readiness':` and change `title` , `lede` , `features` , `perspective` or `faq` . To add a whole new service page:

1. Add an entry to `detailPages` (copy an existing one as a template).
2. Add it to `servicesNav` in `src/data/site.js` so it appears in the menu.
3. Add the slug to `DETAIL_SLUGS` in `src/App.jsx` .
4. Add the route to `ROUTES` in `scripts/prerender.mjs` .

All twelve pages share one template (`src/pages/DetailPage.jsx`), which is why imported Lovable sections look purpose-built rather than bolted on — spacing and type come from the same place as the rest of the site.

Everything else

Page	File
Homepage	<code>src/pages/Home.jsx</code>

Services, Industries, Why TRG, About	src/pages/Simple.jsx
Contact, Resources	src/pages/Contact.jsx
Case studies, Guides, Privacy, Terms, Accessibility, 404	src/pages/Misc.jsx
Header / utility bar	src/components/Header.jsx
Footer	src/components/Footer.jsx
Colours and fonts	tailwind.config.js

To change the brand colour (for example to the purple from the Lovable build), edit the brand palette in tailwind.config.js . That single change recolours every button, link, icon tile, eyebrow and gradient on the site.

2. Building and publishing

```
npm install      # once
npm run build    # produces dist/
```

Upload the contents of dist/ plus the api/ folder to the web root.
The build ships a config file for each kind of host. Only one applies — the others are harmless if left in place:

Host	Config file	Contact form
Apache (cPanel, Hostinger, most shared hosting)	.htaccess	api/contact.php works as shipped
Azure Static Web Apps	staticwebapp.config.json	needs an Azure Function — see below
Azure App Service (Windows / IIS)	web.config	needs an Azure Function or SMTP relay
Azure App Service (Linux, PHP)	.htaccess	api/contact.php works as shipped

Azure does not read .htaccess . That is why the redirect map is repeated in staticwebapp.config.json and web.config . If you change a redirect, change it in all three.

npm run build also pre-renders all 24 pages to real HTML files. Set your domain first so the canonical URLs and sitemap are right:

```
SITE_URL=https://www.trgnetworking.com npm run build
```

If the build says "Pre-render SKIPPED — no browser available", run npx playwright install chromium once, then build again. The site still works without it; crawlers just see less.

Zero-downtime publish

Upload to a new folder next to the live one, check it, then swap. Do not delete the old folder until the new one is confirmed working.

3. The contact form — read this one

The previous Hostinger form wrote submissions into a hidden database table inside the Horizons project and emailed nobody. Visitors saw "Message Sent — a member of our team will be in touch within 2 business hours" while the enquiry sat somewhere no one was watching. Check that old table for unread leads.

The form now posts to api/contact.php , which:

- emails the enquiry to \$NOTIFY_TO , with Reply-To set to the enquirer, so hitting reply goes straight back to them;
- writes a CSV backup to a trg-private/ folder above the web root, so a mail outage never loses a lead;
- rejects invalid emails, silently absorbs bots via a honeypot field, and limits each IP to 5 submissions per 10 minutes;
- never reports success unless the mail actually went out. If sending fails the visitor is shown their message as a pre-filled email plus the phone number, so the lead is not silently dropped.

Two settings to change, both at the top of public/api/contact.php :

```
$NOTIFY_TO    = 'info@trgnetworking.com';    // who receives enquiries
$FROM_ADDRESS = 'website@trgnetworking.com'; // must be a real mailbox ON THIS DOMAIN
```

\$FROM_ADDRESS matters. If it is an address on a domain the server is not authorised to send for, most providers will spam-folder or reject the mail.

This requires PHP, which Azure Static Web Apps and Azure Storage do not run. The form endpoint is set at build time so the code does not have to change:

Whatever it points at needs to answer `{"ok":true}` on success. On Azure the options are an Azure Function that sends through Microsoft 365 (you already have M365, so this is the natural fit), Azure Communication Services Email, or a hosted form service. Tell me which Azure service the site lands on and I will build the matching endpoint.

After going live, send one test enquiry and confirm it arrives.

4. What changed from the two source sites

Brought over from Lovable

- The headline "Simpler IT. Stronger security. A team that responds."
- The top utility bar with phone and "Existing Client Support"
- The four outcome cards ("Less disruption. More confidence.")
- Rewritten, warmer service and industry copy throughout
- The "Multiple eyes on every request" section
- The numbered industry list
- The AI enablement panel ("Use AI with a plan. Not a free-for-all.")
- The three-step "Start with a conversation" process strip
- The dark "TRG perspective" bands
- The FAQ accordions on Managed IT, Cybersecurity and Secure AI
- **Named client testimonials** (see below)
- 8 pages that did not exist on Hostinger: Help Desk, four industry detail pages, Privacy, Terms and Accessibility
- The real LinkedIn URL, the street address and `marketing@` as a contact route

Kept from Hostinger

- The whole design language: blue `#2563EB`, Outfit / Plus Jakarta Sans / Inter, card and button styling, spacing scale
- The photography
- The stats band, partner strip and hero trust badges
- **The contact form** — the only real form on either site
- 3 pages Lovable did not have: Azure Cloud, Case Studies, Guides & Downloads

Fixed along the way

- **Broken image.** The Microsoft section pointed at a Hostinger CDN file that returns 404. Replaced with a real photo.
- **Four dead footer links.** The social icons all pointed at `#` on all 16 pages. Now one working LinkedIn link — placeholders removed rather than left looking broken.
- **Mobile.** The Lovable hero scrolled sideways on a phone; its floating cards hung off the right edge with text cut mid-word. Rebuilt so nothing overflows at any width down to 320px.
- **Invented testimonials.** The Hostinger build carried three quotes from "James R.", "Dr. Patricia M." and "Michael T." — initials only, no company. Replaced with the two attributed quotes from the Lovable build (Nick Pirovolidis, BSC America; Todd Hirsch, Belt Built Contracting). Unverifiable testimonials are a real liability, so I did not carry them across.
- **Empty HTML for crawlers.** Both builds served `<div id="root"></div>` and nothing else. All 24 pages are now pre-rendered — the homepage went from 0 words to over 1,000 in the served source. Added `sitemap.xml`, `robots.txt`, per-page titles, descriptions, canonicals, Open Graph tags and ProfessionalService structured data.
- **URL structure.** The site uses the **Lovable** structure, as requested — service and industry pages sit at the root (`/managed-it-services`, `/construction`). The interim Hostinger slugs 301-redirect to them.
- **Images.** 10 MB of PNGs converted to WebP — now 572 KB total, same quality.
- **Accessibility.** Skip link, visible focus rings, one `<h1>` per page, labelled form fields, alt text, reduced-motion support. The Lovable build shipped an accessibility page; the site now honours it.

Two numbers you should check

The old site claimed **"28+ Years of Experience"** and **"20x7 Monitoring"** while also saying "since 1992". 1992 is 34 years ago, and 20x7 looks like a typo for 24x7. I replaced the years counter with "1992 — serving clients since", which cannot go stale, and set the other to 24x7 to match your own footer. The "163+ organizations served" figure is carried over unchanged — confirm it is still current.

5. Not done / needs a decision

- **Colour.** Lovable is purple, which matches your logo; Hostinger is blue. Your brief said keep Hostinger as the base, so the site is blue. One line in `tailwind.config.js` flips it.
- **Healthcare and Nonprofits** appear on the Industries page as full sections rather than their own pages — Lovable had no copy for them and I would rather not invent it. Give me a few lines each and they become detail pages.
- **Resources downloads** are marked "Coming soon" rather than given buttons that go nowhere. Send me the PDFs and they become real downloads.
- **Case studies** are quotes plus an honest note that write-ups are in progress, rather than invented client stories.

6. Going live on www.trgnetworking.com

www.trgnetworking.com is **not** either of the builds we merged. It is a live WordPress site (theme `designn`, WPBakery Page Builder, Gravity Forms) on third-party hosting — `www` is a CNAME to host.axionthemes.com. There is also a WAF in front of it that blocks unfamiliar crawlers with a 403.

That makes this a site *replacement*, not a first launch. Four things matter.

a. Email will break if the DNS cutover is careless

trgnetworking.com MX records point at **Microsoft 365** (trgnetworking-com.mail.protection.outlook.com). If the domain is moved to new hosting and the DNS is rebuilt from a default template, those MX records are lost and **company email stops**. Whoever performs the cutover must copy MX, SPF, DKIM and any Microsoft verification records across *before* switching.

Nameservers are ns1/ns2/ns3.trgnetworking.com — vanity nameservers. Find out who controls them before scheduling anything.

b. 60 URLs are already indexed

The live sitemap lists 60 URLs: 25 pages and 35 blog posts from 2023–2024. Neither the Hostinger nor the Lovable build contains any of them. Cutting over without a redirect map would 404 all 60 and throw away the site's search history.

`.htaccess` already contains the full map. Every live URL resolves:

Old WordPress URL	New page
/managed-it-services/	<i>same path</i> — ranking carries over directly
/network-security/	/cybersecurity
/cloud-computing/	/microsoft-365-cloud
/data-backup-and-recovery/	/backup-business-continuity
/about-us/	/about
/about-us/contact-us/	/contact
/why-choose-us/	/why-trg
/our-clients/ , /testimonial/*	/resources/case-studies
/free-network-assessment/	/contact?type=assessment
/initial-consultation/ , /discoverycall/	/contact
/itbuyersguide/	/resources/guides
35 blog posts under /YYYY/MM/DD/	/resources (<i>interim</i> — see below)

I simulated every rule against all 60 live URLs plus all 24 new routes: no canonical URL redirects, no loops, nothing 404s. The rules have **not** been executed against a real Apache yet — I will confirm that on the server during cutover.

c. The blog needs a decision

35 posts currently point at [/resources](#) as a holding position. That is honest but it loses their individual rankings. Three options:

1. **Migrate them.** Bring the posts across as real pages. Most work, keeps the most SEO value.
2. **Keep the best.** Migrate the 5–10 that actually earn traffic (pull the list from Google Search Console), redirect the rest.
3. **Leave as is.** Everything lands on Resources. Least work, least value.

Option 2 is usually the right trade. I need Search Console access, or an export, to pick the list.

d. [/support-center/](#) must keep working

It is a live client portal and it is deliberately **not** redirected. Either leave it on the current host or confirm where it moves to before cutover.

Suggested sequence for a zero-downtime switch

1. Publish this build to a staging URL on the target host and check it.

2. Take a full backup of the WordPress site and its database.
3. Confirm MX/SPF/DKIM are recorded somewhere safe.
4. Lower the DNS TTL to 300 seconds, 24 hours ahead.
5. Cut over. Verify the redirect table with real requests.
6. Submit the new [sitemap.xml](#) in Google Search Console.
7. Keep the WordPress backup for at least 30 days.
